# THE DEVELOPMENT OF A CHEMIGATION SYSTEM FOR THE APPLICATION OF DAIRY WASTEWATER

by

Travis C. Kator
Chemigation Engineer
Idaho Department of Agriculture
Boise, Idaho, USA

Written for Presentation at the 1999 ASAE Annual International Meeting Sponsored by ASAE

> Sheraton Centre Hotel Toronto, Ontario Canada July 18-21, 1999

# **Summary:**

The Idaho Law governing chemigation of dairy waste will be discussed to demonstrate what may be required of the dairy facilities in Idaho. Two chemigation systems that are currently in place were evaluated to determine if they met the minimum requirements of the Idaho Pesticide and Chemigation Law for applying dairy wastewater and the method of application for these systems will be discussed. A pilot project is being developed with the cooperation of an Idaho dairyman and commercial dealers to develop a system that will meet the chemigation requirements and apply dairy wastewater in an efficient manner through a center pivot system.

# **Keywords:**

Chemigation, center pivot, effluent, lagoon, land application

# INTRODUCTION

The dairy industry in Idaho has experienced significant changes in the last four years. In 1995, a Memorandum of Understanding (MOU) was signed between the Environmental Protection Agency (EPA), the Idaho Division of Environmental Quality (IDEQ), the Idaho State Department of Agriculture (ISDA), and the Idaho Dairymen's Association (IDA). The MOU transferred waste inspections and rule making authority for dairy facilities in the State of Idaho from IDEQ to ISDA. Through the MOU, ISDA developed a series of rules regarding waste produced on dairy facilities. The first phase of the MOU dealt with waste containment. The next phase deals with the land application of solid and liquid waste that is produced on dairy facilities through the development of Nutrient Management Plans (NMPs). It is quickly becoming apparent that the application of this waste, primarily the liquid waste (i.e. effluent), must be applied in a uniform manner and not be a nuisance to the public. The majority of the effluent has been applied through large sprinkler heads mounted on top of pivots or through wheel/handline. This method typically does not provide a uniform application of effluent nutrients and raises concerns from the public due to odor, aesthetics, and groundwater/surface water pollution.

To address these concerns and potential harm to water, ISDA is beginning to assist the dairymen in determining the best method of applying effluent. In order to provide a more uniform application of nutrients and reduce odor/aesthetic concerns, the effluent needs to be applied at diluted rates through a uniform irrigation. This will require that effluent be mixed with irrigation water and land applied during normal irrigation sets or "chemigating" with dairy effluent. Under the Idaho Pesticide and Chemigation Law (Chapter 34, Title 22, Idaho Code), a chemical is defined as "any fertilizer or pesticide". Fertilizer is defined as "any formulation or product used as a plant nutrient which is intended to promote plant growth and contains one or more plant nutrients". Recently, this definition of fertilizer was interpreted by a State of Idaho Attorney General to include any water from a CAFO/AFO that has come into contact with manure and is collected in a containment structure to later be land applied. The State of Idaho Legislature then attempted to pass a law that included dairy wastewater in the Idaho Pesticide and Chemigation Law. Under this law, dairy effluent when mixed with irrigation water or applied through an irrigation system that is connected to the main water supply, must meet the requirements of the Idaho Pesticide and Chemigation Law and IDAPA 02.03.04 - Rules Governing Chemigation. This law was defeated in the Legislative hearings, but will continue to be an issue until the situation is resolved.

Since this topic will remain a sensitive issue within the Idaho Legislature and with the citizens of Idaho, ISDA is currently developing a chemigation system for the application of dairy effluent. In addition, ISDA will continue to ensure that the dairymen who are applying effluent through irrigation meet the requirements of the Idaho Pesticide and Chemigation Law and IDAPA 02.03.04. The minimum requirements for chemigation under these rules are that the chemical injection line has a quick closing check valve with a solenoid or hydraulically operated valve, a pressure switch, a metering pump, and system interlock. There are additional requirements depending on the type of irrigation system that is being used. In most cases, effluent is being applied through a sprinkler irrigation system that may or may not be connected to a domestic water supply. The sprinkler chemigation systems are required to have an irrigation line check valve with an automatic low-pressure drain, an inspection port, and a vacuum relief valve. If the system is connected to a domestic water supply, the irrigation system line must have a reduced pressure zone backflow preventer (RPZ).

line to the pivot, the system does have a check valve with a combination of an air vent and a vacuum relief valve. However, in order for this system to meet the full requirements of the Idaho Pesticide and Chemigation Law and IDAPA 02.03.04, an inspection port and a low-pressure drain with at least 6 m (20 ft) of hose must be installed on the check valve. A schematic of the existing chemigation system and what will need to be added to correct the system is available in Figure 3 of Appendix A.

CP-2 is a half circle Zimmatic center pivot system that is 274 m (898 ft) long and operates at 30 lps (475 gpm) and 345 kpa (50 psi). Along this pivot, two Nelson SR Series guns have been installed approximately 85m (280 ft) apart. The innermost gun has a nozzle diameter of 1.78 cm (0.7 in) and operates at 6.3 lps (100 gpm). At an optimal performance of 345 kpa (50 psi), this nozzle can cover a diameter of 75 m (245 ft). The outermost gun has a nozzle diameter of 2.29 cm (0.9 in). This will produce a flowrate of 10.2 lps (162 gpm) with a 84 m (275 ft) coverage diameter at 331 kpa (48 psi). As can be seen in the coverage layout in Figure 2 of Appendix A, this pivot also has a coverage distribution problem that has a "doughnut" effect that is more extreme than CP-1.

CP-2's chemigation system is very comparable to that of CP-1. A butterfly valve that is opened manually is located on the effluent line. Again, no chemigation protection equipment is needed along this line. The irrigation line has a check valve with a vacuum relief valve located on the upstream side of the pipe. This system is also missing two components needed to meet the current chemigation regulations. The check valve needs to contain an inspection port and a low-pressure drain with 6 m (20 ft) of hose. The inspection port should be located directly over the low-pressure drain, as can be seen in Figure 3 of Appendix A.

CP-3 is also a half circle Zimmatic center pivot system. It is 462 m (1515 ft) in length and is designed to operate at 345 kpa (50 psi) and 41.6 lps (660 gpm). This pivot has four Nelson SR Series guns spaced every 85 m (280 ft). The innermost gun is operating at 379 kpa (55 psi) with a 1.40 cm (0.55 in) nozzle. The approximate coverage diameter for this nozzle is 63 m (208 ft) at 3.8 lps (61 gpm). Next, there is a 1.65 cm (0.65 in) nozzle operating at 365 kpa (53 psi). At optimal performance this nozzle should produce 5.1 lps (81 gpm) with a coverage diameter of 69 m (226 ft). The second to last gun will cover a diameter of 74 m (243 ft) at 358 kpa (52 psi). This 1.91 cm (0.75 in) nozzle has a flowrate of 6.6 lps (105 gpm). The last nozzle along CP-3 is 2.16 cm (0.85 in) in diameter operating at 348 kpa (50-51 psi). The approximate coverage diameter and flowrate are 83 m (273 ft) and 9.5 lps (150 gpm), respectively. This system also produces the same field effects as CP-1 and CP-2, but to a greater extent since it is a longer pivot with smaller nozzle diameters at the same spacing as CP-1 and CP-2 as seen in Figure 2 of Appendix A.

The chemigation system for CP-3 consists of a butterfly valve on the effluent line with no chemigation protection devices. Once again, this is not a necessity since the effluent is not being mixed and will drain back into the lagoon. The irrigation line contains a gooseneck with the vacuum relief valve located on its apex. Downstream from this point is a booster pump connected to a butterfly valve and a chemigation check valve. However, this check valve does not contain an inspection port or a low-pressure drain. Figure 3 in Appendix A provides a visual aid for determining the system layout. All of the chemigation systems are missing two essential components for a chemigation system to meet current Idaho regulations governing chemigation. Dairy facilities in the state are not currently required to meet these regulations, but will have to in the near future. It was recommended that this dairyman replace his existing chemigation check valves on the irrigation lines at each pivot point to meet current state chemigation regulations.

turbine supply pumps were to shut off and the irrigation water supply pumps and the effluent supply pumps were to continue pumping, the water would enter the lagoon through the overflow pipe before any backflow to the irrigation water sources could occur. The irrigation supply inlet pipes are also set 15-20 cm (6-8 in) above the ground level of the east embankment. This adds another degree of safety in case the overflow pipe could not handle all of the water. The mixing pond water would then overtop the east embankment and run downhill until it reached the lagoon. This would be considered a discharge of effluent, but no major environmental harm or surface water contamination would occur. Also, if the lagoon were to fill up due to overflow, this would cause backflow into the earthen settling ponds. If water were to overfill these settling ponds, it could reach one of the canals, but it would take an excessive amount of water to do so. Figure 2 in Appendix B provides a layout of the mixing pond system. No recommendations were made to alter this system.

The two Treasure Valley Dairy systems will be evaluated for application uniformity using ASAE Standard 436.1. During this testing period, each waste system may be evaluated for solids removal efficiency. Samples would be collected at the pipe inlet of each waste system and after the separation systems. These samples would then be tested for total suspended solids (TSS) in order to determine the true removal efficiency of the system. The nutrient content of the water after it has been land applied may also be tested to determine how the applications compare to chemical fertilizer applications.

After evaluating the Treasure Valley application methods, a preliminary design of a chemigation system was developed for a dairy in the Magic Valley area of Idaho. The Magic Valley Dairy is presently upgrading its waste system to manage 1000 Holstein & Jersey milking cows. There will be approximately a 3:1 ratio of Holsteins to Jerseys. A total of 15% of the milking herd's solid waste will enter the effluent waste stream. The effluent will enter a two-cell concrete, gravity separator, which will remove approximately 60% of the solid particles. The effluent will then be pumped to a storage pond with a storage capacity of 5937 m³ (209,675 ft³). A site layout of the new waste system has been provided in Figure 1 of Appendix C.

The intention of ISDA is to develop a chemigation system that will provide a 10-20% mix of effluent with irrigation water. The present irrigation system consists of a ¾ turn, 50.6 ha (125 acre) center pivot that irrigates both alfalfa and corn silage. It was designed to operate at 483 kpa (70 psi) with a 41 lps (650 gpm) flowrate. Each drop has 138 kpa (20 psi) regulators and Nelson D3000 red plate sprinklers. The pivot is approximately 454 m (1489 ft) in length. The center pivot system pumps irrigation water from a pond located directly south of the pivot point. This water is supplied to the irrigation pond through a pipe connected to an irrigation ditch. The pond, once lined, could work as a mixing pond for the effluent and irrigation water. However, overflow from the irrigation pond would flow to an injection well, which transports this water to another irrigation ditch off of the producer's property. According to the irrigation company, this injection well can not be removed. Therefore, this pond could not be used as a mixing pond.

Due to this, a system very similar to the Treasure Valley #2 (Agri-Lines Irrigation) system will be constructed in order to mix effluent with irrigation water. In the northwest corner of the lagoon, an 2.4 m (8 ft) long section of corrugated steel pipe with a 1.2 m (4 ft) diameter will be placed on end approximately 0.46 m (1.5 ft) deep into a 1.8-m x 1.8-m x 0.61-m (6-ft x 6-ft x 2-ft) concrete slab to form a pump station. Throughout this section of pipe, there will be a series of 1.27 cm (0.5 in) holes to allow effluent to enter the pump station. Within this pipe, wire mesh may be attached over the holes to provide further separation of the solid particles and prevent clogging of the irrigation system. From this pump station, effluent will be pumped into a mixing pond located directly north of the northeast corner of the lagoon using a 1 ½ HP, 5.1 cm (2 in)

PRICTION LOSS THROUGH ENDOUN VALVE IS 1.40 PSI - ENDOUM PRESSURE IS 59.47 PSI COSTER PUMP AT END ADDS 30.00 PSI TO PIPE PRESSURE FOR A PRESSURE OF 60.87 PSI

TOTAL GPM = 1400.42 GPA = 6.76

MINIMUM RECOMMENDED REGULATOR INLET PRESSURE IS 29.00 PSI
WITH GRADUATED ELEVATION OF .00 PT THE INLET PRESSURE IS 36.15 PSI FOR SPRINKLER 116
THIS POSITION IS THE CLUSEST TO THE MINIMUM RECOMMENDED INLET PRESSURE

# CAUTIONS AND WARNINGS—

- uniformity and possible streaking. 1. Inadequate crop clearance and/or structural interference may cause poor water distribution, resulting in decreased
- for proper operation. 2. Over watering at beginning of system due to practical limitations on smallest nozzle sizes available and/or allowable
- mix, due to differences in water pattern and distance of throw 3. Mixing of two or more different sprinkler types usually results in pattern variances at the point where the sprinklers

# CAUTIONS AND WARNINGS:

- Inadequate crop clearance and/or structural interference may cause poor water distribution, resulting in decreased uniformity and possible streaking.
- for proper operation.

2. Over watering at beginning of system due to practical limitations on smallest nozzle sizes available and/or allowable

mb, due to differences in water pattern and distance of throw. 3. Mixing of two or more different sprinkler types usually results in pattern variances at the point where the sprinklers

An ASAE Meeting	g Presentation

# THE DEVELOPMENT OF A CHEMIGATION SYSTEM FOR THE APPLICATION OF DAIRY WASTEWATER

by

Travis C. Kator
Chemigation Engineer
Idaho Department of Agriculture
Boise, Idaho, USA

Written for Presentation at the
Engineering a Sustainable Agricultural and Biological Environment
The 1999 Pacific Northwest Region Meeting
Sponsored by ASAE and CSAE

Sherwood Hills Resort, Logan, Utah September 23-25, 1999

## **Summary:**

The Idaho Law governing chemigation of dairy waste will be discussed to demonstrate what may be required of the dairy facilities in Idaho. Two chemigation systems that are currently in place were evaluated to determine if they met the minimum requirements of the Idaho Pesticide and Chemigation Law for applying dairy wastewater and the method of application for these systems will be discussed. A pilot project is being developed with the cooperation of an Idaho dairyman and commercial dealers to develop a system that will meet the chemigation requirements and apply dairy wastewater in an efficient manner through a center pivot system.

# **Keywords:**

Chemigation, center pivot, effluent, lagoon, land application
